GT25C64

1. Features

- Serial Peripheral Interface (SPI) Compatible
 - Supports Mode 0 (0,0) and Mode 3 (1,1)
- Wide-voltage Operation
 - $V_{CC} = 1.7V$ to $5.5V$
- Low power CMOS
 - Standby current: $\leq 1 \mu A$ ($1.7V$)
 - Operating current: $\leq 3 mA$ ($1.7V$)
- Operating frequency: 20 MHz ($5.5V$)
- Memory organization: 64Kb ($8,192 \times 8$)
- Byte and Page write (up to 32 bytes)
 - Partial page write allowed
- Block Write Protection
 - Protect 1/4, 1/2, or Entire Array
- Self timed write cycle: 5 ms (max.)
- High-reliability
 - Endurance: 1 million cycles
 - Data retention: 100 years
- Industrial temperature grade
- Packages (8-pin): SOIC, TSSOP, UDFN and CSP
- Lead-free, RoHS, Halogen free, Green

2. General Description

The GT25C64 is an industrial standard electrically erasable programmable read only memory (EEPROM) product that utilizes standard Serial Peripheral Interface (SPI) for communications. The GT25C64 contains a memory array of 64K bits ($8,192 \times 8$), which is organized in 32 bytes per page.

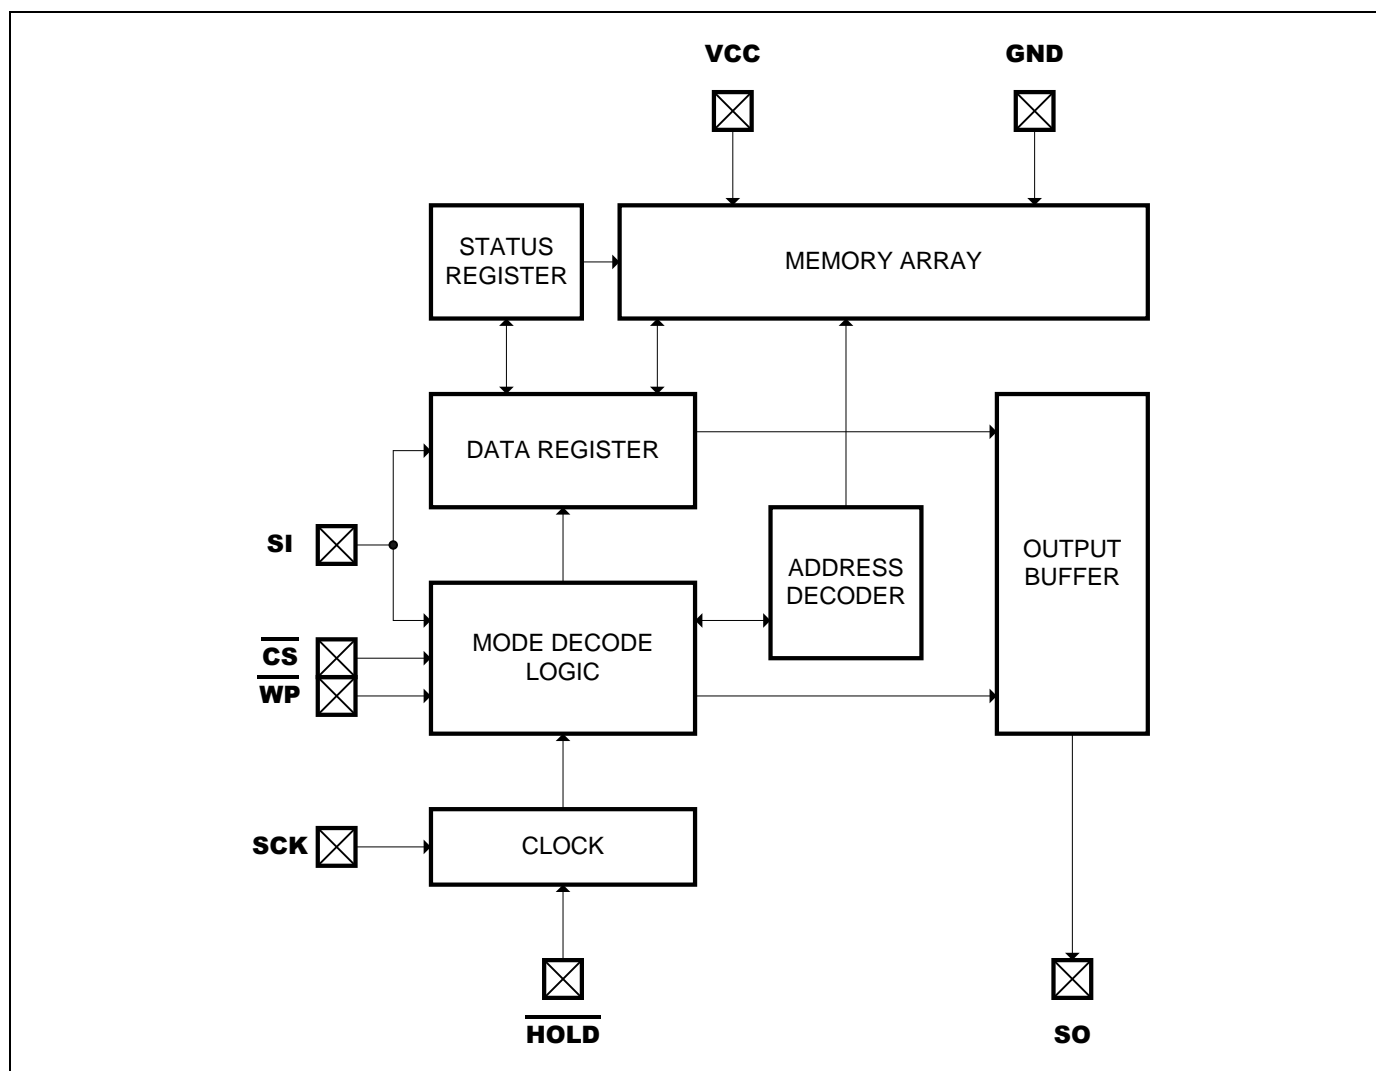

This EEPROM operates in a wide voltage range from 1.7V to 5.5V, which fits most application. The device provides low-power operations and low standby current. The product is offered in Lead-free, RoHS, halogen free or Green package. The available package types are 8-pin SOIC, TSSOP, UDFN and CSP.

The functionalities of the GT25C64 are optimized for most applications, such as consumer electronics, wireless, telecommunication, industrial, medical, instrumentation, commercial and others, where low-power and low-voltage are vital. This product has a compatible SPI interface: Chip-Select (\overline{CS}), Serial Data In (SI), Serial Data Out (SO) and Serial Clock (SCK) for high-speed communication. Furthermore, a Hold feature via \overline{HOLD} pin allows the device entering into a suspended state whenever

necessary and resuming the communication without re-initializing the serial sequence. A Status Register facilitates a flexible write protection mechanism and device status monitoring.

In order to refrain the state machine from entering into a wrong state during power-up sequence or a power toggle off-on condition, a power on reset circuit is implemented. During power-up, the device does not respond to any instructions until the supply voltage (V_{CC}) has reached an acceptable stable level above the reset threshold voltage. Once V_{CC} passes the power on reset threshold, the device is reset and enters into Standby mode. This should also avoid any inadvertent Write operations during power-up stage. During power-down process, the device will enter into standby mode, once V_{CC} drops below the power on reset threshold voltage. In addition, the device will be in standby mode after receiving the Stop command, provided that no internal write operation is in progress. Nevertheless, it is illegal to send a command unless the V_{CC} is within its operating level.

3. Functional Block Diagram

Serial Interface Description

Master:	The device that provides a clock signal.
Slave:	GT25C64.
Transmitter/Receiver:	The GT25C64 has both data input (SI) and data output (SO).
MSB	MSB (Most Significant Bit) is the first bit being transmitted or received.
Op-Code:	Operational instruction code typically sent to the GT25C64 is the first byte of information transmitted after $\overline{\text{CS}}$ is Low. If the Op-Code is a valid instruction as listed in Table 5.3, then it will be decoded appropriately. It is prohibited to send an invalid Op-Code.

GT25C64

4. Pin Configuration

4.1 8-Pin SOIC and TSSOP

4.2 8-Lead UDFN

4.3 Pin Definition

Pin No.	Pin Name	I/O	Definition
1	CS	I	Chip Select
2	SO	O	Serial Data Output
3	WP	I	Write Protect Input
4	GND	-	Ground
5	SI	I	Serial Data Input
6	SCK	I	Serial Clock
7	HOLD	I	Hold function
8	V _{CC}	-	Supply Voltage

4.4 Pin Descriptions

Chip Select ($\overline{\text{CS}}$)

The $\overline{\text{CS}}$ pin is used to enable or disable the device. Upon power-up, $\overline{\text{CS}}$ must follow the supply voltage. When the device is ready for instruction input, this signal requires a High-to-Low transition. Once $\overline{\text{CS}}$ is stable at Low, the device is enabled. Then the master and slave can communicate among each other through SCK, SI, and SO pins. Upon completion of transmission, $\overline{\text{CS}}$ must be driven to High in order to stop the operation or start the internal write operation. The device will enter into standby mode, unless an internal write operation is in progress. During this mode, SO becomes high impedance.

Serial Clock (SCK)

Under the SPI modes (0, 0) and (1, 1), this clock signal provides synchronization between the master and GT25C64. Typically, Op-Codes, addresses and data are latched from SI at the rising edge of SCK, while data from SO are clocked out at the falling edge of SCK.

Serial Data Input (SI)

Data Input pin.

Serial Data Output (SO)

Data output pin.

Write Protect ($\overline{\text{WP}}$)

This active Low input signal is utilized to initiate Hardware Write Protection mode. This mode prevents the Block Protection bits and the WPEN bit in the Status Register from being modified. To activate the Hardware Write Protection, $\overline{\text{WP}}$ must be Low simultaneously when WPEN is set to 1.

Hold (HOLD)

This feature is used to suspend the device in the middle of a serial sequence and temporarily ignore further communication on the bus (SI, SO, SCK). The $\overline{\text{HOLD}}$ signal transitions must occur only when SCK is Low and be held stable during SCK transitions. Connecting $\overline{\text{HOLD}}$ to High disables this feature. Figure. 5-8 shows Hold timing.

GT25C64

5. Device Operation

5.1 Status Register

The Status Register accessible by the user consists of 8-bits data for write protection control and write status. It becomes Read-Only under any of the following conditions:

Hardware Write Protection is enabled or WEN is set to 0. If neither is true, it can be modified by a valid instruction.

Table 5.1: Status Register

Bit	Symbol	Name	Description
0	$\overline{\text{RDY}}$	Ready	When $\overline{\text{RDY}} = 0$, device is ready for an instruction. When $\overline{\text{RDY}} = 1$, device is busy. As busy, device only accepts Read Status Register command.
1	WEN	Write Enable	This represents the write protection status of the device. When WEN = 0, Status Register and entire array cannot be modified, regardless the setting of WPEN, $\overline{\text{WP}}$ pin or block protection. Write Enable command (WREN) can be used to set WEN to 1. Upon power-up stage, WEN is reset to 0.
2	BP0	Block Protect Bit	Despite of the status on WPEN, $\overline{\text{WP}}$ or WEN, BP0 and BP1 configure any combinations of the four blocks being protected (Table 5.2). They are non-volatile memory and programmed to 0 by factory.
3	BP1	Block Protect Bit	
4	X	Don't Care	
5	X	Don't Care	Values can be either 0 or 1, but are not retained. Mostly always 0, except during write operation.
6	X	Don't Care	
7	WPEN	Write Protect Enable	This bit can be utilized to enable Hardware Write Protection, together with $\overline{\text{WP}}$ pin. If enabled, Status Register becomes read-only. However, the memory array is not protected by this mode. Hardware Write Protection requires the setting of $\overline{\text{WP}} = 0$ and WPEN = 1. Otherwise, it is disabled. WPEN cannot be altered from 1 to 0 if $\overline{\text{WP}}$ is already set to Low. (Table 5.4 for write protection)

Note: During internal write cycles, bits 0 to 7 are temporarily 1's.

Table 5.2: Block Protection by BP0 and BP1

Level	Status Register Bits		Array Addresses Protected
	BP1	BP0	
0	0	0	None
1 (1/4)	0	1	1800h-1FFFh
2 (1/2)	1	0	1000h-1FFFh
3 (All)	1	1	0000h-1FFFh

GT25C64

5.2 Op-Code Instructions

The operations of the GT25C64 are controlled by a set of instruction Op-Codes (Table 5.3) that are clocked-in serially via SI pin. To initiate an instruction, the chip select (\overline{CS}) must be Low. Subsequently, each Low-to-High transition of the clock (SCK) will latch a stable level from SI. After the 8-bit Op-Code, it may continue to latch-in an address and/or data from SI accordingly, or to output data from SO. During

data output, data are latched out at the falling edge of SCK. All communications start with MSB first. Upon the transmission of the last bit but prior to any following Low-to-High transition on SCK, \overline{CS} must be brought to High in order to end the transaction and start the operation. The device will enter into Standby Mode after the operation is completed.

Table 5.3: Instruction Op-Codes^[1,2,3]

Name	Op-Code	Operation	Address	Data (SI)	Data (SO)
WREN	0000 X110	Set Write Enable Latch	-	-	-
WRDI	0000 X100	Reset Write Enable Latch	-	-	-
RDSR	0000 X101	Read Status Register	-	-	D ₇ -D ₀ -
WRSR	0000 X001	Write Status Register	-	D ₇ -D ₀	-
READ	0000 X011	Read Data from Array	A ₁₅ -A ₀	-	D ₇ -D ₀ , ...
WRITE	0000 X010	Write Data to Array	A ₁₅ -A ₀	D ₇ -D ₀ , ...	-

Notes: ^[1] X = Don't care bit. However, it is recommended to be "0".

^[2] Some address bits may be don't care (Table 5.5).

^[3] It is strongly recommended that an appropriate format of Op-Code must be entered. Otherwise, it may cause unexpected phenomenon to be occurred. Nevertheless, it is illegal to input invalid any Op-Code.

5.3 Write Enable

When V_{CC} is initially applied, the device powers up with both status register and entire array in a write-disabled state. Upon completion of Write Disable (WRDI), Write Status Register (WRSR) or Write Data to Array (WRITE), the device resets the WEN bit in the Status Register to 0. Prior to any data modification, a Write Enable (WREN) instruction is necessary to set WEN to 1 (Figure. 5-2).

5.4 Write Disable

The device can be completely protected from modification by resetting WEN to 0 through the Write Disable (WRDI) instruction (Figure. 5-3).

5.5 Read Status Register

The Read Status (RDSR) instruction reviews the status of Write Protect Enable, Block Protection setting (Table 5.2), Write Enable state and \overline{RDY} status. RDSR is the only instruction accepted when a write cycle is underway. It is recommended that the status of Write Enable and \overline{RDY} be checked, especially prior to an attempted modification of

data. These 8 bits information can be repeatedly output on SO after the initial Op-Code (Figure. 5-4).

5.6 Write Status Register

The Write Status Register (WRSR) instruction allows the user to choose a Block Protection setting and set or reset the WPEN bit. The values of the other data bits incorporated into WRSR can be 0 or 1 and are not stored in the Status Register. WRSR will be ignored unless both following conditions are true: a) WEN = 1, due to a prior WREN instruction; and b) Hardware Write Protection is not enabled (Table 5.4). Except for \overline{RDY} status, the values in the Status Register remain unchanged until the moment when the write cycle is completed and the register is updated. Note that WPEN can be changed from 1 to 0 only if \overline{WP} is already set High. Once completed, WEN is reset for complete chip write protection (Fig. 5-5).

5.7 Read Data

This instruction includes an Op-Code and 16-bit address, then results the selected data to be shifted out from SO.

GT25C64

Following the first data byte, additional sequential data can be output. If the data byte of the last address is initially output, then address will rollover to the first address in the array, and the output could loop indefinitely. At any time, a rising $\overline{\text{CS}}$ signal ceases the operation (Figure. 5-6).

5.8 Write Data

The WRITE instruction contains an Op-Code, a 16-bit address and the first data byte. Additional data bytes may be supplied sequentially after the first byte. Each WRITE instruction can affect up to 32 bytes of data in a page. Each page has a starting address XXXXXXXX XXX00000 and an ending address XXXXXXXX XXX11111. After the last byte of data in a page is input, the address rolls over to the

beginning of the same page. If more than 32 bytes of data is input during a single instruction, then only the last 32 bytes will be retained, but the initial data will be overwritten.

The contents of the array defined by Block Protection cannot be modified as long as that block configuration is selected. The contents of the array outside the Block Protection can only be modified if Write Enable (WEN) is set to 1. Therefore, it may be necessary that a WREN instruction is initiated prior to WRITE. Once Write operation is completed, WEN is reset for complete chip write protection (Figure. 5-7). Besides, Hardware Write Protection has no affect on the memory array.

Table 5.4: Write Protection

WPEN	$\overline{\text{WP}}$	Hardware Write Protection	WEN	Inside Block	Outside Block	Status Register (WPEN, BP1, BP0)
0	X	Not Enabled	0	Read-only	Read-only	Read-only
0	X	Not Enabled	1	Read-only	Unprotected	Unprotected
1	0	Enabled	0	Read-only	Read-only	Read-only
1	0	Enabled	1	Read-only	Unprotected	Read-only
X	1	Not Enabled	0	Read-only	Read-only	Read-only
X	1	Not Enabled	1	Read-only	Unprotected	Unprotected

Note: X = Don't care bit.
